Overview: We are effectively 3rd party dev for Bob Loblaw (Dr. L), for clin trial.

Needs

How Drug → Immune cell population

No insight into his clinical trial, so lets work back to front.

DATA:

project is always proj1, so we know it is just exp name

subject, describes patient #. → total 3499

Looks like 3 PBMC performed 7 hr interval per patient.

Condition marks sick/healthy. If sick, we view type of cancer present.

↳ Patients likely had to have carcinoma or melanoma when signing up for trial or be healthy (control group).

Age seems to be between 55 → 80

Sex is either gender

Treatment: I do not know how it was decided to do miraclib vs phenximab. Assuming random & this is our exp. But find miraclib online not phenximab Phenximab. Can't tell which is experiment.

Response: I think this is a side effect. Maybe they do an interval dose at 7hr. Based on study therefore, my assumption is initial dose, 30 min for response

Sample: This is just n/3 = patient #. Basically 3 repeats at 7 for int

All cells & My obs:

Even comparing to healthy, I cannot tell by eye what I am supposed to be seeing

→ I think the drugs may act to bring more cd8 cells into localized region, but this is systematic PBMC, so I will refrain from this assumption.
